

### 3 Limit Laws

#### 3.1 Algebra of Limits

We've spent the first couple weeks computing and calculating limits by hand, straight from the definition. By now this has gotten fairly tedious. We'd like to develop some rules, tools, and principles that will allow us to compute limits of functions without going back to the definition.

We start with a few simple simple-to-prove results.

**Lemma 3.1** (Identity). *Let  $a$  be a real number. Then  $\lim_{x \rightarrow a} x = a$ .*

*Proof.* Let  $\epsilon > 0$  and let  $\delta = \epsilon$ . If  $|x - a| < \delta$ , then  $|x - a| < \delta = \epsilon$ . □

**Lemma 3.2** (Almost Identical Functions). *If  $f(x) = g(x)$  on some open interval  $(a-d, a+d)$  surrounding  $a$ , except possibly at  $a$ , then  $\lim_{x \rightarrow a} f(x) = \lim_{x \rightarrow a} g(x)$  whenever one limit exists.*

*Proof.* Suppose  $\lim_{x \rightarrow a} f(x) = L$ . Let  $\epsilon > 0$ ; then there is some  $\delta_1$  such that if  $0 < |x - a| < \delta_1$  then  $|f(x) - L| < \epsilon$ . Then let  $\delta < d, \delta_1$ . If  $0 < |x - a| < \delta$  then  $g(x) = f(x)$ , and thus

$$|g(x) - L| = |f(x) - L| < \epsilon.$$

□

**Exercise 3.3** (Constants). *Prove that if  $a, c$  are real numbers, then  $\lim_{x \rightarrow a} c = c$ .*

*Proof.* See Homework 3. □

Now we can progress to some more complex results. I will prove some of these; I will ask you to prove some; some I won't bother to prove; and some I will wait to prove until later.

**Proposition 3.4.** *Suppose  $c$  is a constant real number, and  $f$  and  $g$  are functions such that  $\lim_{x \rightarrow a} f(x) = L_1$  and  $\lim_{x \rightarrow a} g(x) = L_2$  exist. Then*

1. (Additivity)  $\lim_{x \rightarrow a} (f(x) \pm g(x)) = \lim_{x \rightarrow a} f(x) \pm \lim_{x \rightarrow a} g(x)$ .

*Proof.* Let  $\epsilon > 0$ . Then there exist  $\delta_1, \delta_2 > 0$  such that if  $0 < |x - a| < \delta_1$  then  $|f(x) - L_1| < \epsilon/2$ , and if  $0 < |x - a| < \delta_2$  then  $|g(x) - L_2| < \epsilon/2$ .

Let  $\delta \leq \delta_1, \delta_2$ . Then if  $0 < |x - a| < \delta$ , we compute

$$|f(x) + g(x) - (L_1 + L_2)| = |(f(x) - L_1) + (g(x) - L_2)| \leq |f(x) - L_1| + |g(x) - L_2| < \epsilon/2 + \epsilon/2 = \epsilon.$$

□

2. (Scalar multiples)  $\lim_{x \rightarrow a}(cf(x)) = c \lim_{x \rightarrow a} f(x)$

*Proof.* If  $c = 0$  then the left hand side is  $\lim_{x \rightarrow a} 0 = 0$  and the right hand side is  $0L_1 = 0$  so the equality holds.

If  $c \neq 0$ , then let  $\epsilon > 0$ . Then by definition of limit, there exists some  $\delta$  so that if  $0 < |x - a| < \delta$  then  $|f(x) - L_1| < \epsilon/c$ .

Then if  $0 < |x - a| < \delta$ , we have

$$|cf(x) - cL_1| = c|f(x) - L_1| < c(\epsilon/c) = \epsilon,$$

which is what we wanted to show. □

3. (Products)  $\lim_{x \rightarrow a}(f(x)g(x)) = \lim_{x \rightarrow a} f(x) \cdot \lim_{x \rightarrow a} g(x)$ .

*Proof.* Let  $\epsilon > 0$ . Then there exist  $\delta_1, \delta_2$  such that

- if  $0 < |x - a| < \delta_1$  then  $|f(x) - L_1| < \epsilon/(2|L_2|), 1$ ,
- and if  $0 < |x - a| < \delta_2$  then  $|g(x) - L_2| < \epsilon/(2|L_1| + 2)$ .

Set  $\delta \leq \delta_1, \delta_2$ . Then if  $0 < |x - a| < \delta$ , we compute

$$\begin{aligned} |f(x)g(x) - L_1L_2| &= |f(x)g(x) - f(x)L_2 + f(x)L_2 - L_1L_2| \\ &\leq |f(x)g(x) - f(x)L_2| + |f(x)L_2 - L_1L_2| \\ &= |f(x)| \cdot |g(x) - L_2| + |L_2| \cdot |f(x) - L_1| \\ &= |f(x) - L_1 + L_1| \cdot |g(x) - L_2| + |L_2| \cdot |f(x) - L_1| \\ &\leq (|f(x) - L_1| + |L_1|) \cdot |g(x) - L_2| + |L_2| \cdot |f(x) - L_1| \\ &< (1 + |L_1|) (\epsilon/(2|L_1| + 2)) + |L_2| \cdot \epsilon/(2|L_2|) \\ &= \epsilon/2 + \epsilon/2 = \epsilon. \end{aligned}$$

□

4. (Quotients) That last rule also works with division if that makes sense: if  $\lim_{x \rightarrow a} g(x) \neq 0$ , then

$$\lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \frac{\lim_{x \rightarrow a} f(x)}{\lim_{x \rightarrow a} g(x)}.$$

*Proof.* I'm not going to prove this because it's really long and annoying and not very informative. It's a lot like the last proof except more tedious. If you're feeling masochistic you can probably prove it yourself. □

5. (Exponents) The rule for multiplication extends to exponentials:  $\lim_{x \rightarrow a} (f(x)^n) = (\lim_{x \rightarrow a} f(x))^n$ . Also roots:  $\lim_{x \rightarrow a} \sqrt[n]{f(x)} = \sqrt[n]{\lim_{x \rightarrow a} f(x)}$ , assuming all the functions make sense.

*Proof.* We're only going to prove this for the case of  $f(x)^n$  where  $n$  is a positive integer. The other proofs are basically the same, but this has less bookkeeping.

$$\begin{aligned} \lim_{x \rightarrow a} f(x)^n &= \lim_{x \rightarrow a} f(x) \cdot f(x)^{n-1} \\ &= \left( \lim_{x \rightarrow a} f(x) \right) \left( \lim_{x \rightarrow a} f(x)^{n-1} \right) && \text{by the rule on products} \\ &\vdots \\ &= \left( \lim_{x \rightarrow a} f(x) \right) \cdot \left( \lim_{x \rightarrow a} f(x) \right) \cdots \left( \lim_{x \rightarrow a} f(x) \right) \\ &= \left( \lim_{x \rightarrow a} f(x) \right)^n \end{aligned}$$

Formally we should write this up as a proof by induction. □

**Example 3.5.** 1.

$$\begin{aligned} \lim_{x \rightarrow 1} x^3 &= \left( \lim_{x \rightarrow 1} x \right)^3 && \text{Exponents} \\ &= 1^3 && \text{Identity} \\ &= 1 \end{aligned}$$

2.

$$\begin{aligned} \lim_{x \rightarrow 1} (x+1)^3 - 2 &= \lim_{x \rightarrow 1} (x+1)^3 - \lim_{x \rightarrow 1} 2 && \text{Additivity} \\ &= \left( \lim_{x \rightarrow 1} (x+1) \right)^3 - 2 && \text{Exponents and Constants} \\ &= \left( \lim_{x \rightarrow 1} x + \lim_{x \rightarrow 1} 1 \right)^3 - 2 && \text{Additivity} \\ &= (1+1)^3 - 2 && \text{Identity and Constants} \\ &= 2^3 - 2 = 8 - 2 = 6. \end{aligned}$$

3.

$$\begin{aligned}
 \lim_{x \rightarrow 1} \frac{x^2}{x} &= \frac{\lim_{x \rightarrow 1} x^2}{\lim_{x \rightarrow 1} x} && \text{Quotients} \\
 &= \frac{(\lim_{x \rightarrow 1} x)^2}{\lim_{x \rightarrow 1} x} && \text{Exponents} \\
 &= \frac{1^2}{1} && \text{Identity} \\
 &= 1/1 = 1.
 \end{aligned}$$

We can also approach this problem a different way, since this function is just the same as  $x$  everywhere except at 0:

$$\begin{aligned}
 \lim_{x \rightarrow 1} \frac{x^2}{x} &= \lim_{x \rightarrow 1} x && \text{Almost Identical Functions} \\
 &= 1 && \text{Identity}
 \end{aligned}$$

4.

$$\begin{aligned}
 \lim_{x \rightarrow 0} \frac{x^2}{x} &= \lim_{x \rightarrow 0} x && \text{Almost Identical Functions} \\
 &= 0
 \end{aligned}$$

Unlike the previous problem, we *cannot* use the Quotient property here because the bottom approaches zero. Compare:

$$\begin{aligned}
 \lim_{x \rightarrow 0} \frac{x}{x^2} &= \lim_{x \rightarrow 0} \frac{1}{x} && \text{Almost Identical Functions} \\
 &\neq \frac{\lim_{x \rightarrow 0} 1}{\lim_{x \rightarrow 0} x}
 \end{aligned}$$

The last step doesn't work because now we're dividing by zero, which we can never do. This limit is in fact  $\pm\infty$ , and we'll look at how to show that without a proof from the definition soon.

Of course, even showing all these steps gets tedious, so you don't have to do that unless I explicitly ask you to. It's useful to be able to when you want to check your work carefully, or when you're working with something particularly tricky.

*Poll Question 3.1.1.* What is  $\lim_{x \rightarrow 4} \frac{x^2 - 8x + 16}{x - 4}$ ?

$$\begin{aligned}
\lim_{x \rightarrow 4} \frac{x^2 - 8x + 16}{x - 4} &= \lim_{x \rightarrow 4} \frac{(x - 4)(x - 4)}{x - 4} && \text{arithmetic} \\
&= \lim_{x \rightarrow 4} x - 4 && \text{Almost Identical Functions} \\
&= \lim_{x \rightarrow 4} x - \lim_{x \rightarrow 4} 4 && \text{Additivity} \\
&= 4 - 4 && \text{Identity and Constants} \\
&= 0.
\end{aligned}$$

$$1. \lim_{x \rightarrow -2} \frac{(x+1)^2 - 1}{x+2} = \lim_{x \rightarrow -2} \frac{x^2 + 2x + 1 - 1}{x+1} = \lim_{x \rightarrow -2} \frac{x(x+2)}{x+2} = \lim_{x \rightarrow -2} x = -2.$$

Note that  $\frac{x(x+2)}{x+2} \neq x$ , but their limits at 0 are the same because the functions are the same near 0 (and in fact everywhere except at 0).

$$2. \text{ What is } \lim_{x \rightarrow 0} \frac{\sqrt{9+x} - 3}{x}?$$

We use a trick called multiplication by the conjugate, which takes advantage of the fact that  $(a + b)(a - b) = a^2 - b^2$ . This trick is used *very often* so you should get comfortable with it.

$$\begin{aligned}
\lim_{x \rightarrow 0} \frac{\sqrt{9+x} - 3}{x} &= \lim_{x \rightarrow 0} \frac{\sqrt{9+x} - 3}{x} \frac{\sqrt{9+x} + 3}{\sqrt{9+x} + 3} \\
&= \lim_{x \rightarrow 0} \frac{(9+x) - 3}{x(\sqrt{9+x} + 3)} = \lim_{x \rightarrow 0} \frac{x}{x(\sqrt{9+x} + 3)} \\
&= \lim_{x \rightarrow 0} \frac{1}{\sqrt{9+x} + 3} = \frac{1}{\lim_{x \rightarrow 0} \sqrt{9+x} + 3} = \frac{1}{6}.
\end{aligned}$$

$$3. \text{ What is } \lim_{x \rightarrow 1} \frac{x-1}{\sqrt{5-x}-2}?$$

$$\begin{aligned}
\lim_{x \rightarrow 1} \frac{x-1}{\sqrt{5-x}-2} &= \lim_{x \rightarrow 1} \frac{x-1}{\sqrt{5-x}-2} \frac{\sqrt{5-x}+2}{\sqrt{5-x}+2} \\
&= \lim_{x \rightarrow 1} \frac{(x-1)(\sqrt{5-x}+2)}{(5-x)-4} \\
&= \lim_{x \rightarrow 1} \frac{(x-1)(\sqrt{5-x}+2)}{-(x-1)} \\
&= \lim_{x \rightarrow 1} -(\sqrt{5-x}+2) = -4.
\end{aligned}$$

**Proposition 3.6** (Two-sided limits).  $\lim_{x \rightarrow a} f(x) = L$  if and only if  $\lim_{x \rightarrow a^-} f(x) = L = \lim_{x \rightarrow a^+} f(x)$ . In particular the two-sided limit exists if and only if both one-sided limits exist and are the same.

*Proof.* Suppose  $\lim_{x \rightarrow a} f(x) = L$ . Let  $\epsilon > 0$ ; then there is a  $\delta > 0$  such that if  $0 < |x - a| < \delta$  then  $|f(x) - L| < \epsilon$ . Then if  $a - \delta < x < a$ , we know that  $|x - a| < \delta$  and thus  $|f(x) - L| < \epsilon$ , so  $\lim_{x \rightarrow a^-} f(x) = L$  by definition. Similarly if  $a < x < a + \delta$  then  $0 < |x - a| < \delta$  and thus  $|f(x) - L| < \epsilon$ , so  $\lim_{x \rightarrow a^+} f(x) = L$ .

Conversely, suppose  $\lim_{x \rightarrow a^-} f(x) = L = \lim_{x \rightarrow a^+} f(x)$ . Let  $\epsilon > 0$ . Then there is a  $\delta_1$  so that if  $a - \delta_1 < x < a$  then  $|f(x) - L| < \epsilon$ . And there is a  $\delta_2$  so that if  $a < x < a + \delta_2$  then  $|f(x) - L| < \epsilon$ .

So let  $\delta \leq \delta_1, \delta_2$ . Then if  $0 < |x - a| < \delta$ , either  $a - \delta_1 < x < a$  or  $a < x < a + \delta_2$ , and either way  $|f(x) - L| < \epsilon$ .  $\square$

**Example 3.7.** Let  $f(x) = \begin{cases} \frac{x^2 + 4x + 3}{x + 1} & x < -1 \\ x^2 + 1 & x > -1 \end{cases}$ . What is  $\lim_{x \rightarrow -1} f(x)$ ?

We can take the left and right limits separately.

$$\begin{aligned} \lim_{x \rightarrow -1^-} f(x) &= \lim_{x \rightarrow -1^-} \frac{x^2 + 4x + 3}{x + 1} = \lim_{x \rightarrow -1^-} x + 3 = (-1) + 3 = 2. \\ \lim_{x \rightarrow -1^+} f(x) &= \lim_{x \rightarrow -1^+} x^2 + 1 = 2. \end{aligned}$$

Since the one-sided limits exist and are equal, we have  $\lim_{x \rightarrow -1} f(x) = 2$ .

**Example 3.8.** Let  $g(x) = \begin{cases} \frac{x^2 + x - 6}{x - 2} & x < 2 \\ \frac{\sqrt{3x + 10} - 4}{x - 2} & x > 2 \end{cases}$ . What is  $\lim_{x \rightarrow 2} g(x)$ ?

We can take the left and right limits separately. We have

$$\begin{aligned} \lim_{x \rightarrow 2^-} g(x) &= \lim_{x \rightarrow 2^-} \frac{x^2 + x - 6}{x - 2} = \lim_{x \rightarrow 2^-} x + 3 = 5 \\ \lim_{x \rightarrow 2^+} g(x) &= \lim_{x \rightarrow 2^+} \frac{\sqrt{3x + 10} - 4}{x - 2} = \lim_{x \rightarrow 2^+} \frac{\sqrt{3x + 10} - 4}{x - 2} \cdot \frac{\sqrt{3x + 10} + 4}{\sqrt{3x + 10} + 4} \\ &= \lim_{x \rightarrow 2^+} \frac{3x + 10 - 16}{(x - 2)(\sqrt{3x + 10} + 4)} = \lim_{x \rightarrow 2^+} \frac{3(x - 2)}{(x - 2)(\sqrt{3x + 10} + 4)} \\ &= \lim_{x \rightarrow 2^+} \frac{3}{\sqrt{3x + 10} + 4} = \frac{3}{8}. \end{aligned}$$

The left and right limits are not equal, so the limit does not exist.

## 3.2 Limit Laws at Infinity

We'll start by talking about cases where the limit is finite, even though we're letting  $x$  tend to infinity. In these cases the limit exists, so exactly the same limit laws apply.

We do need one additional principle, to correspond to our identity law. We recall that  $\lim_{x \rightarrow +\infty} \frac{1}{x} = 0$ ; this will be enough to do basically everything we want to do.

**Example 3.9.** If we want to calculate  $\lim_{x \rightarrow +\infty} \frac{1}{\sqrt{x}}$ , we see that

$$\lim_{x \rightarrow +\infty} \frac{1}{\sqrt{x}} = \sqrt{\lim_{x \rightarrow +\infty} \frac{1}{x}} = \sqrt{0} = 0.$$

**Example 3.10.** What is  $\lim_{x \rightarrow +\infty} \frac{x}{x^2+1}$ ?

This problem illustrates the primary technique we'll use to solve infinite limits problems. It's difficult to deal with problems that have variables in the numerator and denominator, so we want to get rid of at least one. Thus we will divide out by  $x$ s on the top and the bottom until one has none left:

$$\lim_{x \rightarrow +\infty} \frac{x}{x^2+1} = \lim_{x \rightarrow +\infty} \frac{x/x}{x^2/x+1/x} = \lim_{x \rightarrow +\infty} \frac{1}{x+\frac{1}{x}} = \lim_{x \rightarrow +\infty} \frac{1}{x} = 0.$$

**Example 3.11.** Some more examples of this technique:

$$\begin{aligned} \lim_{x \rightarrow -\infty} \frac{x}{x+1} &= \lim_{x \rightarrow -\infty} \frac{1}{1+\frac{1}{x}} = \lim_{x \rightarrow -\infty} \frac{1}{1} = 1. \\ \lim_{x \rightarrow -\infty} \frac{x}{3x+1} &= \lim_{x \rightarrow -\infty} \frac{1}{3+\frac{1}{x}} = \frac{1}{3}. \end{aligned}$$

**Example 3.12.** What is  $\lim_{x \rightarrow +\infty} \frac{x^{3/2}}{\sqrt{9x^3+1}}$ ? This one is a bit tricky. We want to divide the top and bottom by  $x^{3/2}$ . Then we can pull the factor *inside* the square root sign.

$$\lim_{x \rightarrow +\infty} \frac{x^{3/2}}{\sqrt{9x^3+1}} = \lim_{x \rightarrow +\infty} \frac{1}{\sqrt{9+1/x^{3/2}}} = \frac{1}{\sqrt{9+0}} = \frac{1}{3}.$$

**Example 3.13.** Sometimes it's a bit harder to see how this works. For instance, what is  $\lim_{x \rightarrow +\infty} \frac{x}{\sqrt{x^2+1}}$ ? It's not obvious, but we use the same technique:

$$\lim_{x \rightarrow +\infty} \frac{x}{\sqrt{x^2+1}} = \lim_{x \rightarrow +\infty} \frac{x/x}{\sqrt{x^2+1}/x} = \lim_{x \rightarrow +\infty} \frac{1}{\sqrt{x^2/x^2+1/x^2}} = \lim_{x \rightarrow +\infty} \frac{1}{\sqrt{1+\frac{1}{x^2}}} = 1.$$

**Example 3.14.** What is  $\lim_{x \rightarrow -\infty} \frac{x}{\sqrt{x^2+1}}$ ?

We can do the same thing, but we have to be *very careful*. Remember that if  $x < 0$  then  $\sqrt{x^2} \neq x$ ! Instead,  $x = -\sqrt{x^2}$ . Thus we have

$$\lim_{x \rightarrow -\infty} \frac{x}{\sqrt{x^2+1}} = \lim_{x \rightarrow -\infty} \frac{1}{\sqrt{x^2+1}/x} = \lim_{x \rightarrow -\infty} \frac{1}{-\sqrt{1+\frac{1}{x^2}}} = -1.$$

When we encounter new functions, one of the ways we will often want to characterize them is by computing their limits at  $\pm\infty$ . Sometimes these limits do not exist.

**Example 3.15.**  $\lim_{x \rightarrow +\infty} \sin(x)$  does not exist, since the function oscillates rather than settling down to one limit value.

$\lim_{x \rightarrow +\infty} x \sin(x)$  also does not exist; this function oscillates more and more wildly as  $x$  increases.

We shall see later on that  $\lim_{x \rightarrow +\infty} \frac{1}{x} \sin(x)$  exists.

Another technique that will also often appear in these limits is combining a sum or difference into one fraction. If we have a sum of two terms that both have infinite limits, we need to combine or factor them into one term to see what is happening.

**Example 3.16.** What is  $\lim_{x \rightarrow +\infty} \sqrt{x^2 + 1} - x$ ?

We might want to try to use limit laws here, but we would get  $+\infty - +\infty$  which is not defined (and is one of the classic indeterminate forms). Instead we need to combine our expressions into one big fraction.

$$\begin{aligned} \lim_{x \rightarrow +\infty} \sqrt{x^2 + 1} - x &= \lim_{x \rightarrow +\infty} \left( \sqrt{x^2 + 1} - x \right) \frac{\sqrt{x^2 + 1} + x}{\sqrt{x^2 + 1} + x} \\ &= \lim_{x \rightarrow +\infty} \frac{(x^2 + 1) - x^2}{\sqrt{x^2 + 1} + x} = \lim_{x \rightarrow +\infty} \frac{1}{\sqrt{x^2 + 1} + x}. \end{aligned}$$

The numerator is 1 and the denominator approaches  $+\infty$  so the limit is 0. This tells us that as  $x$  increases,  $x$  and  $\sqrt{x^2 + 1}$  get as close together as we wish.

You may have noticed the appearance of our old friend, multiplication by the conjugate. We will often use that technique in this sort of problem.

**Example 3.17.** What is  $\lim_{x \rightarrow +\infty} \sqrt{x^2 + x + 1} - x$ ?

$$\begin{aligned} \lim_{x \rightarrow +\infty} \sqrt{x^2 + x + 1} - x &= \lim_{x \rightarrow +\infty} \left( \sqrt{x^2 + x + 1} - x \right) \frac{\sqrt{x^2 + x + 1} + x}{\sqrt{x^2 + x + 1} + x} \\ &= \lim_{x \rightarrow +\infty} \frac{x^2 + x + 1 - x^2}{\sqrt{x^2 + x + 1} + x} = \lim_{x \rightarrow +\infty} \frac{x + 1}{\sqrt{x^2 + x + 1} + x} \\ &= \lim_{x \rightarrow +\infty} \frac{1 + 1/x}{\sqrt{1 + 1/x + 1/x^2} + 1} = \frac{1}{2}. \end{aligned}$$

### 3.3 Infinite limits

Now we want to talk about infinite limits, that is, limits where the output increases without bound.

**Lemma 3.18.** *Let  $f(x), g(x)$  be defined near  $a$ , such that  $\lim_{x \rightarrow a} f(x) = c \neq 0$  and  $\lim_{x \rightarrow a} g(x) = 0$ . Then*

$$\lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \pm\infty.$$

*Further, assuming  $c > 0$  then the limit is  $+\infty$  if and only if  $g(x) \geq 0$  near  $a$ , and the limit is  $-\infty$  if and only if  $g(x) \leq 0$  near  $a$ . If  $c < 0$  then the opposite is true.*

*Remark 3.19.* If the limit of the numerator is zero, then this lemma is *not useful*. That is one of the “indeterminate forms” which requires more analysis before we can compute the limit completely.

*Proof.* Let  $N > 0$ . Then there’s a  $\delta_1$  so that if  $0 < |x - a| < \delta_1$  then  $|f(x) - c| < c/2$  and thus in particular  $f(x) > c/2$ . And there’s a  $\delta_2$  so that if  $0 < |x - a| < \delta_2$  then  $|g(x)| < c/2N$ .

Let  $\delta \leq \delta_1, \delta_2$ . Then if  $0 < |x - a| < \delta$  we have

$$\left| \frac{f(x)}{g(x)} \right| = \frac{|f(x)|}{|g(x)|} > \frac{c/2}{|g(x)|} > \frac{c/2}{c/2N} = N.$$

□

**Example 3.20.** What is  $\lim_{x \rightarrow 3} \frac{-1}{\sqrt{x-3}}$ ? We see the top goes to 1 and the bottom goes to 0, so the limit is  $\pm\infty$ . Since the denominator is always positive and the numerator is negative, the limit is  $-\infty$ .

We have to be careful while working these problems: the limit laws that work for finite limits don’t always work here, since the limit laws assume that the limits exist, and these do not. In particular, adding and subtracting infinity *does not work*.

**Example 3.21.** We already know that  $\lim_{x \rightarrow 0} 1/x = \pm\infty$ .

1. If we take  $\lim_{x \rightarrow 0} 1/x - 1/x$ , we could say the limit is  $\pm\infty - \pm\infty$ , but this is silly—the limit is actually 0.
2. In contrast,  $\lim_{x \rightarrow 0} 1/x + 1/x = \lim_{x \rightarrow 0} 2/x = \pm\infty$ . We don’t add the infinities together.

3. And  $\lim_{x \rightarrow 0} 1/x + 1/x^2$  is the trickiest. We have a  $\pm\infty$  plus a  $+\infty$ . But again we can't add infinities—we need to combine them into one term.

$$\lim_{x \rightarrow 0} \frac{1}{x} + \frac{1}{x^2} = \lim_{x \rightarrow 0} \frac{x+1}{x^2} = +\infty$$

since the numerator approaches 1 and the denominator approaches 0, but is always positive.

We could heuristically say that  $\frac{1}{x^2}$  goes to  $+\infty$  “faster” than  $\frac{1}{x}$  goes to  $\pm\infty$ , and so it wins out; but this is really vague and handwavy so we try to replace it with more precise arguments like this one.

**Example 3.22.** What is  $\lim_{x \rightarrow -2} \frac{1}{x+2} + \frac{2}{x(x+2)}$ ? This looks like  $\infty + \infty$  so we have to be careful. We have

$$\begin{aligned} \lim_{x \rightarrow -2} \frac{1}{x+2} + \frac{2}{x(x+2)} &= \lim_{x \rightarrow -2} \frac{x}{x+2} + \frac{2}{x(x+2)} \\ &= \lim_{x \rightarrow -2} \frac{x+2}{x(x+2)} = \lim_{x \rightarrow -2} \frac{1}{x} = \frac{-1}{2}. \end{aligned}$$

**Example 3.23.** What is  $\lim_{x \rightarrow -\infty} x - x^3$ ?

Each term goes to  $-\infty$ , so this is a difference of infinities and thus indeterminate. But we can factor:  $\lim_{x \rightarrow -\infty} x(1 - x^2)$ . The first term goes to  $-\infty$  and the second term also goes to  $-\infty$ , so their product will go to  $+\infty$ . Thus  $\lim_{x \rightarrow -\infty} x - x^3 = +\infty$ .

If I want to be really careful, I can argue:

$$\lim_{x \rightarrow -\infty} x - x^3 = \lim_{x \rightarrow -\infty} \frac{x - x^3}{1} = \lim_{x \rightarrow -\infty} \frac{1/x^2 - 1}{1/x^3}.$$

We see the limit of the top is  $-1$  and the limit of the bottom is 0, so the limit of the whole is  $\pm\infty$ . In fact the bottom will always be negative (since  $x \rightarrow -\infty$ ), and thus the limit is  $+\infty$ .

Multiplying infinities does *sort of* work, but multiplying infinity by 0 is unpredictable.

**Example 3.24.** 1.  $\lim_{x \rightarrow 1} \frac{1}{x-1} = \pm\infty$  and  $\lim_{x \rightarrow 1} \frac{1}{(x-1)^2} = +\infty$ , so  $\lim_{x \rightarrow 1} \frac{1}{(x-1)^3} = \lim_{x \rightarrow 1} \frac{1}{x-1} \cdot \frac{1}{(x-1)^2} = \pm\infty$ . We could also see this directly, since  $(x-1)^3$  approaches zero, and can be positive or negative.

2.  $\lim_{x \rightarrow -2} (x+2) = 0$  and  $\lim_{x \rightarrow -2} \frac{1}{x+2} = \pm\infty$ .  $\lim_{x \rightarrow -2} (x+2) \frac{1}{x+2} = \lim_{x \rightarrow -2} 1 = 1$ . But  $\lim_{x \rightarrow -2} (x+2) \frac{1}{(x+2)^2} = \pm\infty$  and  $\lim_{x \rightarrow -2} (x+2)^2 \frac{1}{x+2} = 0$ .

3. The same thing happens when the input tends to infinity:

$$\lim_{x \rightarrow +\infty} \frac{x^2}{x+1} = \lim_{x \rightarrow +\infty} \frac{1}{1/x + \frac{1}{x^2}}.$$

The limit of the top is 1 and the limit of the bottom is 0, so the limit is  $\pm\infty$ . And the bottom will always be positive since  $x \rightarrow +\infty$ , so the entire limit is  $+\infty$ .

**Example 3.25.**  $\lim_{x \rightarrow 3^+} \frac{1}{(x-3)^3} = +\infty$ : the limit of the top is 1, and the limit of the bottom is 0, so the limit is  $\pm\infty$ . But when  $x > 3$  the denominator is  $\geq 0$ , so the limit is in fact  $+\infty$ . Conversely  $\lim_{x \rightarrow 3^-} \frac{1}{(x-3)^3} = -\infty$  since when  $x < 3$  we have  $(x-3)^3 \leq 0$ .

$\lim_{x \rightarrow -1^+} \frac{1}{(x+1)^4} = +\infty$ . And  $\lim_{x \rightarrow -1^-} \frac{1}{(x+1)^4} = +\infty$ . Thus  $\lim_{x \rightarrow -1} \frac{1}{(x+1)^4} = +\infty$ .

**Definition 3.26.** If  $\lim_{x \rightarrow a} f(x) = \pm\infty$ , then we say that the line  $x = a$  is a *vertical asymptote* of the curve  $y = f(x)$ .

We will sometimes refer to “intedeterminate forms,” including  $0/0$ ,  $\infty/\infty$ ,  $0 \cdot \infty$ ,  $\infty + \infty$ ,  $1^\infty$ , and  $\infty^0$ . Importantly, none of these are actual numbers, and they are never the correct answer to any question. These are simply forms that indicate you have more work to do; a limit that appears to be  $0/0$  can in fact converge to anything or fail to converge, depending on specifics.

In contrast,  $0/1$  is a possibly valid answer and you’re done.  $1/0$  is not literally a number, and “ $1/0$ ” is never the correct answer to anything. But it does suggest that the limit is infinite, and we can use the techniques above to make that precise.

### 3.4 Trigonometric Limits and the Squeeze Theorem

We now want to look at limits of trigonometric functions. We will state the following proposition without proof:

**Proposition 3.27.** *If  $a$  is a real number, then  $\lim_{x \rightarrow a} \sin(x) = \sin(a)$  and  $\lim_{x \rightarrow a} \cos(x) = \cos(a)$ .*

In fact, since trigonometric functions are just ways of combining sine and cosine, essentially all trigonometric functions behave this way where defined.

Recall we previously saw that  $\lim_{x \rightarrow 0} \sin(1/x)$  does not exist.

In contrast, from the graph it appears that  $\lim_{x \rightarrow 0} x \sin(1/x)$  does exist. To prove this we will need:

Figure 3.1: Left: graph of  $\sin(1/x)$ , Right: graph of  $x \sin(1/x)$ 

**Theorem 3.28** (Squeeze Theorem). *If  $f(x) \leq g(x) \leq h(x)$  near  $a$  (except possibly at  $a$ ), and  $\lim_{x \rightarrow a} f(x) = \lim_{x \rightarrow a} h(x) = L$ , then  $\lim_{x \rightarrow a} g(x) = L$ .*

Now we see that since  $-1 \leq \sin(1/x) \leq 1$ , we can write

$$-|x| \leq x \sin(1/x) \leq |x|$$

But  $\lim_{x \rightarrow 0} (-|x|) = \lim_{x \rightarrow 0} |x| = 0$  and so by the squeeze theorem,  $\lim_{x \rightarrow 0} x \sin(1/x) = 0$ .

Figure 3.2: A graph of  $x \sin(1/x)$  with  $|x|$  and  $-|x|$ 

**Example 3.29.** Show that  $\lim_{x \rightarrow 3} (x-3) \frac{x^2}{x^2+1} = 0$ .

We know that  $0 \leq x^2 \leq x^2 + 1$  and so  $0 \leq \frac{x^2}{x^2+1} \leq 1$  for any  $x$ . Thus

$$-|x-3| \leq (x-3) \frac{x^2}{x^2+1} \leq |x-3|.$$

(We need the absolute value signs so that this statement is true if  $x < 3$  as well).

Then  $\lim_{x \rightarrow 3} |x-3| = \lim_{x \rightarrow 3} -|x-3| = 0$ , and so by the squeeze theorem  $\lim_{x \rightarrow 3} (x-3) \frac{x^2}{x^2+1} = 0$ .

**Example 3.30.** What is

$$\lim_{x \rightarrow 1} \frac{x-1}{2 + \sin\left(\frac{1}{x-1}\right)}?$$

The top goes to zero and the bottom is bounded, so this looks like a squeeze theorem problem.

We know that  $-1 \leq \sin\left(\frac{1}{x-1}\right) \leq 1$  and so  $1 \leq 2 + \sin\left(\frac{1}{x-1}\right) \leq 3$ , and thus

$$\begin{aligned} 1 &\geq \frac{1}{2 + \sin\left(\frac{1}{x-1}\right)} \geq \frac{1}{3} \\ |x-1| &\geq \frac{|x-1|}{2 + \sin\left(\frac{1}{x-1}\right)} \geq \frac{|x-1|}{3} \\ |x-1| &\geq \left| \frac{x-1}{2 + \sin\left(\frac{1}{x-1}\right)} \right| \geq \frac{|x-1|}{3} \end{aligned}$$

since the denominator is always positive. But  $\lim_{x \rightarrow 1} |x-1| = \lim_{x \rightarrow 1} \frac{|x-1|}{3} = 0$ , so by the squeeze theorem

$$\lim_{x \rightarrow 1} \left| \frac{x-1}{2 + \sin\left(\frac{1}{x-1}\right)} \right| = 0.$$

But if the absolute value goes to zero, the function goes to zero, and thus

$$\lim_{x \rightarrow 1} \frac{x-1}{2 + \sin\left(\frac{1}{x-1}\right)} = 0.$$

Figuring out the bounds here can be kind of tricky, but we can simplify things with one additional tool:

**Proposition 3.31.** *Suppose  $f$  is defined near  $a$ . Then  $\lim_{x \rightarrow a} f(x) = 0$  if and only if  $\lim_{x \rightarrow a} |f(x)| = 0$ .*

This helps us because it lets us work entirely inside the absolute value signs, thus letting us avoid any concerns about the sign.

**Example 3.32** (Continued). Above we could reason that

$$\begin{aligned} \frac{1}{3} &\leq \left| \frac{1}{2 + \sin\left(\frac{1}{x-1}\right)} \right| \leq 1 \\ \frac{|x-1|}{3} &\leq \left| \frac{x-1}{2 + \sin\left(\frac{1}{x-1}\right)} \right| \leq |x-1|. \end{aligned}$$

Then  $\lim_{x \rightarrow 1} \frac{|x-1|}{3} = \lim_{x \rightarrow 1} |x-1| = 0$ , so by the squeeze theorem,

$$\lim_{x \rightarrow 1} \left| \frac{x-1}{2 + \sin\left(\frac{1}{x-1}\right)} \right| = 0.$$

Thus we know that

$$\lim_{x \rightarrow 1} \frac{x-1}{2 + \sin\left(\frac{1}{x-1}\right)} = 0.$$

**Example 3.33.** What is  $\lim_{x \rightarrow -1} (x+1) \cos\left(\frac{x^5 - 3x^2 + e^x - 1700 + (2+x)^{(1+x)^x}}{(x+1)^{27.2}}\right)$ ?

This looks complicated but is actually quite simple.  $-1 \leq \cos(y) \leq 1$  for any  $y$ , including  $y = x^5 - 3x^2 + e^x - 1700 + x^{x^x}$ . Thus we have

$$\begin{aligned} 0 &\leq |\cos(y)| \leq 1 \\ 0 &\leq |(x+1)\cos(y)| \leq |x+1|. \end{aligned}$$

Then we know that  $\lim_{x \rightarrow -1} 0 = \lim_{x \rightarrow -1} |x+1| = 0$ . Thus by the squeeze theorem,

$$\lim_{x \rightarrow -1} |(x+1)\cos(x^5 - 3x^2 + e^x - 1700 + x^{x^x})| = 0,$$

and thus

$$\lim_{x \rightarrow -1} (x+1)\cos(x^5 - 3x^2 + e^x - 1700 + x^{x^x}) = 0.$$

**Example 3.34.** What is

$$\lim_{x \rightarrow 0} \frac{x-1}{2 + \sin\left(\frac{1}{x-1}\right)}?$$

This is a trick question. Here we have no concerns about zeroes in the denominator or points outside of the domain, we can repeatedly apply limit laws:

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{x-1}{2 + \sin\left(\frac{1}{x-1}\right)} &= \frac{\lim_{x \rightarrow 0} (x-1)}{\lim_{x \rightarrow 0} 2 + \sin\left(\frac{1}{x-1}\right)} \\ &= \frac{-1}{2 + \sin\left(\lim_{x \rightarrow 0} \frac{1}{x-1}\right)} \\ &= \frac{-1}{2 + \sin(-1)} = \frac{-1}{2 - \sin(1)}. \end{aligned}$$

**Example 3.35.**  $\lim_{x \rightarrow +\infty} \frac{\sin(x)}{x}$  exists, by the squeeze theorem.

For large  $x$  we have  $\frac{-1}{x} \leq \frac{\sin(x)}{x} \leq \frac{1}{x}$ , and  $\lim_{x \rightarrow +\infty} \frac{-1}{x} = \lim_{x \rightarrow +\infty} \frac{1}{x} = 0$ . So by the squeeze theorem  $\lim_{x \rightarrow +\infty} \frac{\sin(x)}{x} = 0$ .

You might notice this is *exactly the same proof* we gave for  $\lim_{x \rightarrow 0} x \sin(1/x)$ . This is not a coincidence, since the two functions are the same after the substitution  $y = 1/x$ .

There is one more important limit involving sin:

**Proposition 3.36** (Small Angle Approximation).

$$\lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} = 1$$

*Proof.* We'll assume  $\theta$  is small and positive; this all still works if  $\theta$  is small and negative, with different signs. Our diagram is of a circle with radius 1.

Let  $\theta$  be the measure of angle AOC in our diagram. Observe that  $\sin \theta$  is precisely the length of the line segment AC by definition, and so triangle BOC has area  $\sin \theta/2$ . The area of the entire circle is  $\pi$  and so the area of the wedge from B to C is  $\pi\theta/2\pi = \theta/2$ . Since the triangle is contained in the wedge, we have  $\sin \theta/2 \leq \theta/2$  and thus  $\sin \theta/\theta \leq 1$ .

Note that AC is  $\sin \theta$  and AO is  $\cos \theta$ , so AC over AO is  $\sin(\theta)/\cos(\theta) = \tan(\theta)$ . By similarity, we have  $DB = \tan \theta$ , and the area of triangle BOD is  $\tan \theta/2$ . Since the wedge from B to C is contained in this triangle, we have  $\theta/2 \leq \tan \theta/2$  and thus  $\cos \theta \leq \sin \theta/\theta$ .

Thus  $\cos \theta \leq \frac{\sin \theta}{\theta} \leq 1$ . But  $\lim_{\theta \rightarrow 0} \cos \theta = 1$ , so by the squeeze theorem we have

$$1 \leq \lim_{\theta \rightarrow 0} \frac{\sin \theta}{\theta} \leq 1$$

and thus get the desired result. □

**Example 3.37.**  $\lim_{x \rightarrow 0} \frac{\sin(2x)}{2x} = 1$ .

**Example 3.38.** What is  $\lim_{x \rightarrow 0} \frac{\sin(4x)\sin(6x)}{\sin(2x)x}$ ?

We can write

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{\sin(4x)\sin(6x)}{\sin(2x)x} &= \lim_{x \rightarrow 0} \frac{\sin(4x)/4x \cdot \sin(6x)/6x \cdot 24x^2}{\sin(2x)/2x \cdot 2x \cdot x} \\ &= \lim_{x \rightarrow 0} \frac{\sin 4x}{4x} \cdot \frac{\sin 6x}{6x} \cdot \frac{2x}{\sin(2x)} \cdot \frac{24x^2}{2x^2} \\ &= 1 \cdot 1 \cdot 1 \cdot 12 = 12. \end{aligned}$$

Here we are simply pairing off the  $\sin(y)$ 's with  $ys$  and then collecting the remainder into the last term.

**Example 3.39.**  $\lim_{x \rightarrow 0} \csc x = \pm\infty$  since  $\csc(x) = \frac{1}{\sin(x)}$ ; the top goes to 1, and the bottom goes to 0 two-sidedly.

$$\lim_{x \rightarrow 1} (x-1) \csc(x-1) = \lim_{x \rightarrow 1} \frac{x-1}{\sin(x-1)} = 1 \text{ by the small angle approximation.}$$

*Poll Question 3.4.1.* What is  $\lim_{x \rightarrow 0} \frac{x \sin(2x)}{\tan(3x)}$ ?

When we see a tangent in a problem, it is often helpful to rewrite it in terms of sin and cos. We can then collect terms:

$$\begin{aligned} \lim_{x \rightarrow 0} \frac{x \sin(2x)}{\tan(3x)} &= \lim_{x \rightarrow 0} \frac{x \sin(2x)}{\sin(3x) / \cos(3x)} \\ &= \lim_{x \rightarrow 0} \frac{3x}{\sin 3x} \cdot \frac{\sin(2x) \cos(3x)}{3} = 1 \cdot \frac{0}{3} = 0. \end{aligned}$$
