

Lab 7 Thursday March 29

Euler's Method

Download the file `euler.nb` from the course web page, and evaluate the first block of code. This will give you four functions.

`euler[df,x0,y0,xfin,n]` uses Euler's method to approximate $f(x_{fin})$ given the initial data $y' = df, f(x_0) = y_0$ and n steps. It outputs the estimate of $f(x_{fin})$.

`eulerplot[df,x0,y0,xfin,n]` runs the same approximation, but instead of reporting the estimate as a number, it plots the data points.

`compareplot[f_, x0_, y0_, xfin_, n_]` takes a known function and plots that function on the domain $[x_0, x_{fin}]$; against it it plots the data points generated by using Euler's method to estimate $f(x_{fin})$ with the initial data $f(x_0) = y_0$, but computing the true derivative at every point.

`comparewitherrors[f_, df_, x0_, y0_, xfin_, n_]` plots $f(x)$ on $[x_0, x_{fin}]$ as before. But instead of comparing to Euler's method with the true derivative, it compares to Euler's method as estimated with the differential equation $y' = df$.

1. Consider the example equation $f'(t) = f(t) - f(t)^2/2$ with $f(0) = 1$.
 - (a) Use the command `euler[y - y^2/2, 0, 1, 3, 3]` to estimate $f(3)$ given $y' = y - y^2/2$ and $f(0) = 1$, with three steps. How does this compare to the answer we got before?
 - (b) Use the command `eulerplot[y - y^2/2, 0, 1, 3, 3]` to see these results graphically.
 - (c) Now try using nine steps, with `euler[y - y^2/2,0,1,3,9]`. What changes? Do the same with `eulerplot`
 - (d) Now try using 100 steps.

2. Now let's play around with the comparison plot. We already looked at $\sin(x)$.

Now let's consider the function $f(x) = e^x$. We haven't studied this function in class yet, but it's a fact that it satisfies the differential equation $y' = y$.

- (a) Use the functions `compareplot[E^x, 0, 1, 5, 5]` and `comparewitherrors[E^x,y, 0,1,5,5]` to compare the actual function to the results of Euler's method.
 - (b) Why did we pick the initial values we did?
 - (c) Which approximation is better? Why?
 - (d) Try again with 10 steps instead of 5. Try 100 steps. Play around and see what happens as you change the step size.
3. Another important differential equation is the *logistic growth equation*, which is often used to model population growth. The differential equation is $y' = y(1 - y)$ and the corresponding function is $f(x) = \frac{1}{1 + \frac{1-x_0}{x_0} e^{-x}}$ or `L[x_] := 1 / (1 + (1-x0)/x0 E^(-x))`, where x_0 is the initial condition
 - (a) We'll take the initial condition $x_0 = 1/2$. (This corresponds to a population at 50% of maximum capacity). This gives the function `L[x_] := 1/(1 + E^(-x))`
 - (b) Use the command `compareplot[1/(1+E^(-x)),0,.5,10,10]` to estimate $L(10)$. What happens?

- (c) What if we raise the step size to 100?
- (d) Now let's compare to the differential equation. Use the command `comparewitherrors[1/(1 + E^(-x)), y (1 - y), 0, .5, 10, 10]` to use Euler's method to fit the equation. What happens? How is this different from before?
- (e) Increase the step size to 100.
4. Let's look at the same function with different initial conditions.
- (a) We'll take the initial condition $x_0 = 2$, corresponding to a population at double capacity. This gives the function $L[x_] := 1/(1 - E^(-x)/2)$.
- (b) Use the command `compareplot[1/(1-E^(-x)/2),0,2,10,10]` to estimate $L(10)$. What happens?
- (c) What if we raise the step size to 100? To 1000?
- (d) Now let's compare to the differential equation. Use the command `comparewitherrors[1/(1 - E^(-x)/2), y (1 - y), 0, 2, 10, 10]` to use Euler's method to fit the equation. What happens? How is this different from before?
- (e) Increase the step size to 100. To 1000.
- (f) Does using the "true" derivative, or the differential equation, work better? Why do you think this is?
5. The differential equation $y' = y - e^x \sin(5x)/2 + 5e^x \cos(5x)$ with initial conditions $y(0) = 0$ has solution $y = e^x \sin(5)$.
- (a) Run `compareplot[E^x Sin[5x],0,0,10,10]`. What happens?
- (b) Try with 100 steps. Try with 1000.
- (c) Run `comparewitherrors[E^x Sin[5x],y-E^x Sin[5x]/2+5E^x Cos[5x],0,0,10,10]`
- (d) Try with 100 steps. Try with 1000.
6. If we take $y' = 2y/x - x^2y^2$, you can check that $f(x) = \frac{5x^2}{x^5+4}$ is a solution, with initial condition $f(1) = 1$.
- (a) Use the command `compareplot[5x^2/(x^5+4),1,1,5,5]` to estimate $L(5)$. What happens?
- (b) What if we raise the number of steps to 10? To 100?
- (c) Now let's compare to the differential equation. Use the command `comparewitherrors[5 x^2/(x^5 + 4), 2 y/x - x^2 y^2, 1, 1, 5, 10]` to use Euler's method to fit the equation. What happens? How is this different from before?
- (d) Increase the step size to 100. To 1000.

Implicit Functions and their Tangents

When using the `ContourPlot` command, note the double `==` signs.

1. In class, we showed that the tangent line to $x^3 + y^3 = 6xy$ at the point $(3, 3)$ is $y - 3 = 3 - x$. Verify this with the command `ContourPlot[{x^3 + y^3 == 6 x*y, y-3 == 3 -x}, {x,-5,5},{y,-5,5}]`

2. (a) Use ContourPlot to plot the "cardioid" with equation:
 $x^2 + y^2 == (2x^2 + 2y^2 - x)^2$. (x and y domains from -1 to 1).
- (b) Compute the derivative at the point $(0, 1/2)$ by running the commands
 $D[x^2 + y[x]^2 == (2x^2 + 2y[x]^2 - x)^2, x]$ and
 $D[x^2 + y[x]^2 == (2x^2 + 2y[x]^2 - x)^2, x] /. y[x] -> 1/2 /. x -> 0$

Note some important details here. Mathematica can't figure out that y is a function of x instead of a constant unless we tell it, so we write $y[x]$ instead of y . We can have Mathematica automatically substitute for us, but it matters that we do $/. y[x] -> 1/2$ before $/. x -> 0$. Why? Try it the other way and see what happens.

- (c) Plot the tangent line to the cardioid at that point in Mathematica.
- (d) What do you expect to happen if you try to find the tangent line at $(0, 0)$? Are you right? What does Mathematica say?
- (e) Looking at the graph, what do you think is the tangent line at the point $(1, 0)$? Can you get this from your derivative formula? Try computing the (implicit) derivative with respect to y instead of x . What happens?
3. (a) Plot the "devil's curve" $y^2(y^2 - 4) == x^2(x^2 - 5)$
- (b) Compute the derivative at $(0, -2)$.
- (c) Plot the devil's curve and its tangent line simultaneously.
- (d) Run the command
 $ContourPlot[y^2(y^2-4) - x^2(x^2 -5), {x, -5, 5}, {y, -5, 5}]$ What happens? Why?
4. (a) Plot $(x^2 + y^2 - 1)^3 - x^2 * y^3 == 0$
- (b) Check that $(1, 1)$ is a solution to this equation, and compute the derivative at $(1, 1)$.
- (c) Plot the tangent line.
- (d) Now try plotting without the equals sign, as in (3).
5. (a) Plot $\text{Sin}[x^2 + y^2] == \text{Cos}[x * y]$ from -5 to 5 .
- (b) As before, replace the $==$ with a $-$ sign.

Just Because They're Pretty

1. Some other functions to try:
 - $\text{Sin}[\text{Sin}[x] + \text{Cos}[y]] == \text{Cos}[\text{Sin}[x * y] + \text{Cos}[y]]$
 - $\text{Abs}[\text{Sin}[x^2 - y^2]] == \text{Sin}[x + y] + \text{Cos}[x * y]$
 - $\text{Csc}[1-x^2] * \text{Cot}[2-y^2] == x * y$
 - $\text{Abs}[\text{Sin}[x^2 + 2 * x * y]] == \text{Sin}[x - 2 y]$
 - $(x^2 + y^2 - 3) \text{Sqrt}[x^2 + y^2] + .75 + \text{Sin}[4 \text{Sqrt}[x^2 + y^2]]$
 $\text{Cos}[84 \text{ArcTan}[y/x]] - \text{Cos}[6 \text{ArcTan}[y/x]] == 0$
2. Try replacing the $==$ signs with $-$ signs.
3. Look at the examples on the Wolfram Alpha page
<https://www.wolframalpha.com/examples/PopularCurves.html>
